The one dimensional heat equation: Neumann and Robin boundary conditions

Ryan C. Daileda

Partial Differential Equations
February 28, 2012
The heat equation with Neumann boundary conditions

Our goal is to solve:

\[ u_t = c^2 u_{xx}, \quad 0 < x < L, \ 0 < t, \]  
\[ u_x(0, t) = u_x(L, t) = 0, \quad 0 < t, \]  
\[ u(x, 0) = f(x), \quad 0 < x < L. \]

As before, we will use **separation of variables** to find a family of simple solutions to (1) and (2), and then the **principle of superposition** to construct a solution satisfying (3).
Assuming that $u(x, t) = X(x) T(t)$, the heat equation (1) becomes

$$XT' = c^2 X'' T.$$ 

This implies

$$\frac{X''}{X} = \frac{T'}{c^2 T} = k,$$

which we write as

$$X'' - kX = 0, \quad (4)$$

$$T' - c^2 k T = 0. \quad (5)$$

The initial conditions (2) become $X'(0) T(t) = X'(L) T(t) = 0$, or

$$X'(0) = X'(L) = 0. \quad (6)$$
Case 1: $k = \mu^2 > 0$

The ODE (4) becomes $X'' - \mu^2 X = 0$ with general solution

$$X = c_1 e^{\mu x} + c_2 e^{-\mu x}.$$

The boundary conditions (6) are

$$0 = X'(0) = \mu c_1 - \mu c_2 = \mu(c_1 - c_2),$$
$$0 = X'(L) = \mu c_1 e^{\mu L} - \mu c_2 e^{-\mu L} = \mu(c_1 e^{\mu L} - c_2 e^{-\mu L}).$$

The first gives $c_1 = c_2$. When we substitute this into the second we get

$$2c_1 \mu \sinh \mu L = 0.$$

Since $\mu, L > 0$, we must have $c_1 = c_2 = 0$. Hence $X = 0$, i.e. there are only trivial solutions in the case $k > 0$. 

Daileda
Case 2: $k = 0$

The ODE (4) is simply $X'' = 0$ so that

$$X = Ax + B.$$ 

The boundary conditions (6) yield

$$0 = X'(0) = X'(L) = A.$$ 

Taking $B = 1$ we get the solution

$$X_0 = 1.$$ 

The corresponding equation (5) for $T$ is $T' = 0$, which yields $T = C$. We set

$$T_0 = 1.$$ 

These give the zeroth normal mode:

$$u_0(x, t) = X_0(x)T_0(t) = 1.$$ 

Daileda The heat equation
Case 3: \( k = -\mu^2 < 0 \)

The ODE (4) is now \( X'' + \mu^2 X = 0 \) with solutions

\[
X = c_1 \cos \mu x + c_2 \sin \mu x.
\]

The boundary conditions (6) yield

\[
0 = X'(0) = -\mu c_1 \sin 0 + \mu c_2 \cos 0 = \mu c_2,
\]

\[
0 = X'(L) = -\mu c_1 \sin \mu L + \mu c_2 \cos \mu L.
\]

The first of these gives \( c_2 = 0 \). In order for \( X \) to be nontrivial, the second shows that we also need

\[
\sin \mu L = 0.
\]
Case 3: $k = -\mu^2 < 0$

This can occur if and only if $\mu L = n\pi$, that is

$$\mu = \mu_n = \frac{n\pi}{L}, \quad n = \pm 1, \pm 2, \pm 3, \ldots$$

Choosing $c_1 = 1$ yields the solutions

$$X_n = \cos \mu_n x, \quad n = 1, 2, 3, \ldots$$

For each $n$ the corresponding equation (5) for $T$ becomes

$$T' = -\lambda_n^2 T, \quad \text{with} \quad \lambda_n = c\mu_n.$$  Up to a constant multiple, the solution is

$$T_n = e^{-\lambda_n^2 t}.$$
Normal modes and superposition

Multiplying these together gives the \textit{nth normal mode}

\[
    u_n(x, t) = X_n(x) T_n(t) = e^{-\lambda_n^2 t} \cos \mu_n x, \quad n = 1, 2, 3, \ldots
\]

where \( \mu_n = n\pi/L \) and \( \lambda_n = c\mu_n \).

The principle of superposition now guarantees that for any choice of constants \( a_0, a_1, a_2, \ldots \)

\[
    u(x, t) = a_0 u_0 + \sum_{n=1}^{\infty} a_n u_n = a_0 + \sum_{n=1}^{\infty} a_n e^{-\lambda_n^2 t} \cos \mu_n x \quad (7)
\]

is a solution of the heat equation (1) with the Neumann boundary conditions (2).
Initial conditions

If we now require that the solution (7) satisfy the initial condition (3) we find that we need

\[ f(x) = u(x, 0) = a_0 + \sum_{n=1}^{\infty} a_n \cos \frac{n\pi x}{L}, \quad 0 < x < L. \]

This is simply the \textit{cosine series expansion of} \( f(x) \). Using our previous results, we finally find that if \( f(x) \) is piecewise smooth then

\[ a_0 = \frac{1}{L} \int_0^L f(x) \, dx, \quad a_n = \frac{2}{L} \int_0^L f(x) \cos \frac{n\pi x}{L} \, dx, \quad n \geq 1. \]
Conclusion

Theorem

If \( f(x) \) is piecewise smooth, the solution to the heat equation (1) with Neumann boundary conditions (2) and initial conditions (3) is given by

\[
 u(x, t) = a_0 + \sum_{n=1}^{\infty} a_n e^{-\lambda_n^2 t} \cos \mu_n x,
\]

where

\[
 \mu_n = \frac{n\pi}{L}, \quad \lambda_n = c\mu_n,
\]

and the coefficients \( a_0, a_1, a_2, \ldots \) are those occurring in the cosine series expansion of \( f(x) \). They are given explicitly by

\[
 a_0 = \frac{1}{L} \int_{0}^{L} f(x) \, dx, \quad a_n = \frac{2}{L} \int_{0}^{L} f(x) \cos \frac{n\pi x}{L} \, dx, \quad n \geq 1.
\]
Example 1

Solve the following heat conduction problem:

\[ u_t = \frac{1}{4} u_{xx}, \quad 0 < x < 1, \quad 0 < t, \]
\[ u_x(0, t) = u_x(1, t) = 0, \quad 0 < t, \]
\[ u(x, 0) = 100x(1 - x), \quad 0 < x < 1. \]

With \( L = 1, \mu_n = n\pi \) and \( f(x) = 100x(1 - x) \) we find

\[ a_0 = \int_0^1 100x(1 - x) \, dx = \frac{50}{3} \]

\[ a_n = 2 \int_0^1 100x(1 - x) \cos n\pi x \, dx = \frac{-200(1 + (-1)^n)}{n^2\pi^2}, \quad n \geq 1. \]
Example 1

Since $c = 1/2$, $\lambda_n = n\pi/2$. Plugging everything into our general solution we get

$$u(x, t) = \frac{50}{3} - \frac{200}{\pi^2} \sum_{n=1}^{\infty} \frac{(1 + (-1)^n)}{n^2} e^{-n^2\pi^2 t/4} \cos n\pi x.$$ 

As in the case of Dirichlet boundary conditions, the exponential terms decay rapidly with $t$. We have

$$\lim_{t \to \infty} u(x, t) = \frac{50}{3}.$$
Remarks

- At any given time, the *average temperature* in the bar is

  \[ \bar{u}(t) = \frac{1}{L} \int_0^L u(x, t) \, dx. \]

- In the case of Neumann boundary conditions, one has

  \[ \bar{u}(t) = a_0 = \bar{f}. \]

  That is, *the average temperature is constant and is equal to the initial average temperature*.

- Also in this case

  \[ \lim_{t \to \infty} u(x, t) = a_0 \]

  for all \( x \). That is, at any point in the bar *the temperature tends to the initial average temperature*. 
We now consider the problem

\[ u_t = c^2 u_{xx}, \quad 0 < x < L, \quad 0 < t, \]
\[ u(0, t) = 0, \quad 0 < t, \quad (8) \]
\[ u_x(L, t) = -\kappa u(L, t), \quad 0 < t, \quad (9) \]
\[ u(x, 0) = f(x), \quad 0 < x < L. \]

- In (9) we take \( \kappa > 0 \). This states that the bar radiates heat to its surroundings at a rate proportional to its current temperature.
- Recall that conditions such as (9) are called Robin conditions.
As before, the assumption that $u(x, t) = X(x)T(t)$ leads to the ODEs

\begin{align*}
X'' - kX &= 0, \\
T' - c^2kT &= 0,
\end{align*}

and the boundary conditions (8) and (9) imply

\begin{align*}
X(0) &= 0, \\
X'(L) &= -\kappa X(L).
\end{align*}

Also as before, the possibilities for $X$ depend on the sign of the separation constant $k$. 
Case 1: \( k = 0 \)

We have \( X'' = 0 \) and so \( X = Ax + B \) with

\[
0 = X(0) = B,
\]
\[
A = X'(L) = -\kappa X(L) = -\kappa (AL + B).
\]

Together these give \( A(1 + \kappa L) = 0 \). Since \( \kappa, L > 0 \), we have \( A = 0 \) and hence \( X = 0 \). Thus,

\[
\text{there are only trivial solutions in this case.}
\]
Case 2: $k = \mu^2 > 0$

Once again we have $X'' - \mu^2 X = 0$ and

$$X = c_1 e^{\mu x} + c_2 e^{-\mu x}.$$ 

The boundary conditions become

$$0 = c_1 + c_2,$$

$$\mu(c_1 e^{\mu L} - c_2 e^{-\mu L}) = -\kappa(c_1 e^{\mu L} + c_2 e^{-\mu L}).$$

The first gives $c_2 = -c_1$, which when substituted in the second yields

$$2\mu c_1 \cosh \mu L = -2\kappa c_1 \sinh \mu L.$$
Case 2: $k = \mu^2 > 0$

We may rewrite this as

$$c_1 (\mu \cosh \mu L + \kappa \sinh \mu L) = 0.$$  

The quantity in parentheses is positive (since $\mu$, $\kappa$ and $L$ are), so this means we must have $c_1 = -c_2 = 0$. Hence $X = 0$ and

there are only trivial solutions in this case.
Case 3: $k = -\mu^2 < 0$

From $X'' + \mu^2 X = 0$ we find

$$X = c_1 \cos \mu x + c_2 \sin \mu x$$

and from the boundary conditions we have

$$0 = c_1,$$
$$\mu (-c_1 \sin \mu L + c_2 \cos \mu L) = -\kappa (c_1 \cos \mu L + c_2 \sin \mu L).$$

Together these imply that

$$c_2 (\mu \cos \mu L + \kappa \sin \mu L) = 0.$$
Case 3: $k = -\mu^2 < 0$

Since we want nontrivial solutions (i.e. $c_2 \neq 0$), we must have

$$\mu \cos \mu L + \kappa \sin \mu L = 0$$

which can be rewritten as

$$\tan \mu L = -\frac{\mu}{\kappa}.$$ 

This equation has an infinite sequence of positive solutions

$$0 < \mu_1 < \mu_2 < \mu_3 < \cdots$$
Case 3: $k = -\mu^2 < 0$

The figure below shows the curves $y = \tan \mu L$ (in red) and $y = -\mu/\kappa$ (in blue).

The $\mu$-coordinates of their intersections (in pink) are the values $\mu_1$, $\mu_2$, $\mu_3$, \ldots
Remarks

From the diagram we see that:

- For each $n$

\[(2n - 1)\pi/2L < \mu_n < n\pi/L.\]

- As $n \to \infty$

\[\mu_n \to (2n - 1)\pi/2L.\]

- Smaller values of $\kappa$ and $L$ tend to accelerate this convergence.
Normal modes

As in the earlier situations, for each $n \geq 1$ we have the solution

$$X_n = \sin \mu_n x$$

and the corresponding

$$T_n = e^{-\lambda_n^2 t}, \quad \lambda_n = c\mu_n$$

which give the **normal modes** of the heat equation with boundary conditions (8) and (9)

$$u_n(x, t) = X_n(x) T_n(t) = e^{-\lambda_n^2 t} \sin \mu_n x.$$
Superposition

Superposition of normal modes gives the **general solution**

\[ u(x, t) = \sum_{n=1}^{\infty} c_n u_n(x, t) = \sum_{n=1}^{\infty} c_n e^{-\lambda_n^2 t} \sin \mu_n x. \]

Imposing the initial condition \( u(x, 0) = f(x) \) gives us

\[ f(x) = \sum_{n=1}^{\infty} c_n \sin \mu_n x. \]

This is a **generalized Fourier series** for \( f(x) \). It is *different* from the ordinary sine series for \( f(x) \) since

\( \mu_n \) is not a multiple of a common value.
Generalized Fourier coefficients

To compute the generalized Fourier coefficients $c_n$ we will use the following fact.

**Proposition**

The functions

$$X_1(x) = \sin \mu_1 x, \quad X_2(x) = \sin \mu_2 x, \quad X_3(x) = \sin \mu_3 x, \ldots$$

form a complete orthogonal set on $[0, L]$.

- *Complete* means that all “sufficiently nice” functions can be represented via generalized Fourier series. This is a consequence of **Sturm-Liouville theory**, which we will study later.

- We can verify orthogonality directly, and will use this to express the coefficients $c_n$ as ratios of inner products.
Generalized Fourier coefficients

Assuming orthogonality for the moment, for any $n \geq 1$ we have the familiar computation

\[
\langle f, X_n \rangle = \left\langle \sum_{m=1}^{\infty} c_m \sin \mu_m x, \sin \mu_n x \right\rangle \\
= \sum_{m=1}^{\infty} c_m \langle \sin \mu_m x, \sin \mu_n x \rangle \\
= c_n \langle \sin \mu_n x, \sin \mu_n x \rangle \\
= c_n \langle X_n, X_n \rangle
\]

since the inner products with $m \neq n$ all equal zero.
It follows immediately that the generalized Fourier coefficients are given by

\[ c_n = \frac{\langle f, X_n \rangle}{\langle X_n, X_n \rangle} = \frac{\int_0^L f(x) \sin \mu_n x \, dx}{\int_0^L \sin^2 \mu_n x \, dx}. \]

- For any given \( f(x) \) these integrals can typically be computed explicitly in terms of \( \mu_n \).
- The values of \( \mu_n \), however, must typically be found via numerical methods.
The solution to the heat equation (1) with Robin boundary conditions (8) and (9) and initial condition (3) is given by

$$u(x, t) = \sum_{n=1}^{\infty} c_n e^{-\lambda_n^2 t} \sin \mu_n x,$$

where $\mu_n$ is the $n$th positive solution to

$$\tan \mu L = \frac{-\mu}{\kappa},$$

$$\lambda_n = c \mu_n,$$

and the coefficients $c_n$ are given by

$$c_n = \frac{\int_0^L f(x) \sin \mu_n x \, dx}{\int_0^L \sin^2 \mu_n x \, dx}.$$
Example 2

**Example**

Solve the following heat conduction problem:

\[ \begin{align*}
    u_t &= \frac{1}{25} u_{xx}, & 0 < x < 3, & 0 < t, \\
    u(0, t) &= 0, & 0 < t, \\
    u_x(3, t) &= -\frac{1}{2} u(3, t), & 0 < t, \\
    u(x, 0) &= 100 \left( 1 - \frac{x}{3} \right), & 0 < x < 3.
\end{align*} \]

We have \( c = 1/5, \ L = 3, \ \kappa = 1/2 \) and \( f(x) = 100(1 - x/3). \)
Example 2

The integrals defining the Fourier coefficients are

\[ 100 \int_{0}^{3} \left(1 - \frac{x}{3}\right) \sin \mu_n x \, dx = \frac{100(3\mu_n - \sin 3\mu_n)}{3\mu_n^2} \]

and

\[ \int_{0}^{3} \sin^2 \mu_n x \, dx = \frac{3}{2} + \cos^2 3\mu_n. \]

Hence

\[ c_n = \frac{200(3\mu_n - \sin 3\mu_n)}{3\mu_n^2 (3 + 2 \cos^2 3\mu_n)}. \]
Example 2

We can therefore write out the full solution as

\[
    u(x, t) = \sum_{n=1}^{\infty} \frac{200(3\mu_n - \sin 3\mu_n)}{3\mu_n^2 (3 + 2 \cos^2 3\mu_n)} e^{-\mu_n^2 t/25} \sin \mu_n x,
\]

where \(\mu_n\) is the \(n\)th positive solution to \(\tan 3\mu = -2\mu\).
Example 2

Remarks:

- In order to use this solution for numerical approximation or visualization, we must compute the values $\mu_n$.

- This can be done numerically in Maple, using the `fsolve` command. Specifically, $\mu_n$ can be computed via the command:

  ```maple
  fsolve(tan(m*L)=-m/k, m=(2*n-1)*Pi/(2*L)..n*Pi/L);
  ```

  where $L$ and $k$ have been assigned the values of $L$ and $\kappa$, respectively.

- These values can be computed and stored in an `Array` structure, or one can define $\mu_n$ as a function using the `->` operator.
Example 2

Here are approximate values for the first 5 values of $\mu_n$ and $c_n$.

<table>
<thead>
<tr>
<th>$n$</th>
<th>$\mu_n$</th>
<th>$c_n$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.7249</td>
<td>47.0449</td>
</tr>
<tr>
<td>2</td>
<td>1.6679</td>
<td>45.1413</td>
</tr>
<tr>
<td>3</td>
<td>2.6795</td>
<td>21.3586</td>
</tr>
<tr>
<td>4</td>
<td>3.7098</td>
<td>19.3403</td>
</tr>
<tr>
<td>5</td>
<td>4.7474</td>
<td>12.9674</td>
</tr>
</tbody>
</table>

Therefore

$$u(x, t) = 47.0449e^{-0.0210t} \sin(0.7249x) + 45.1413e^{-0.1113t} \sin(1.6679x)$$
$$+ 21.3586e^{-0.2872t} \sin(2.6795x) + 19.3403e^{-0.5505t} \sin(3.7098x)$$
$$+ 12.9674e^{-0.9015t} \sin(4.7474x) + \cdots$$
